Data Over Cable System Interface Specification  
Quality of Service  
Management Information Base (DOCSIS-QoS MIB)

Status of This Memo

This document specifies an Internet standards track protocol for the Internet community, and requests discussion and suggestions for improvements. Please refer to the current edition of the "Internet Official Protocol Standards" (STD 1) for the standardization state and status of this protocol. Distribution of this memo is unlimited.

Abstract

This document defines a basic set of managed objects for SNMP-based management of extended QoS features of Cable Modems (CMs) and Cable Modem Termination Systems (CMTSs) conforming to the Data over Cable System (DOCSIS) specifications versions 1.1 and 2.0.

### 1. Introduction

This memo is a product of the IP over Cable Data Network (IPCDN) working group within the Internet Engineering Task Force (IETF).

#### 1.1. The Internet-Standard Management Framework

For a detailed overview of the documents that describe the current Internet-Standard Management Framework, please refer to section 7 of RFC 3410 [15].

Managed objects are accessed via a virtual information store, termed the Management Information Base or MIB. MIB objects are generally accessed through the Simple Network Management Protocol (SNMP). Objects in the MIB are defined using the mechanisms defined in the Structure of Management Information (SMI). This memo specifies a MIB module that is compliant to the SMIv2, which is described in STD 58, RFC 2578 [1], STD 58, RFC 2579 [2] and STD 58, RFC 2580 [3].

## 1.2. Glossary

Active QPS	Active QoS Parameter Set (QPS). The set of QoS parameters that describe the current level of service provided to a Service Flow (SF).
Active SF	Active Service Flow. An SF with a non-empty Active QPS.
Admitted QPS	Admitted QoS Parameter Set. The set of QoS parameters that describe a level of service that the Service Flow is not currently using, but that it is guaranteed to receive upon the SF's request to make the set Active.
Admitted SF	A Service Flow with a non-empty Admitted QPS.
CATV	Cable Television.
CM	Cable Modem. A modem connecting a subscriber's LAN to the Cable Television (CATV) Radio Frequency (RF) network. DOCSIS CMs operate as a MAC layer bridge between the home LAN and the Cable Television (CATV) Radio Frequency (RF) network.
CMTS	Cable Modem Termination System. The "head-end" device providing connectivity between the RF network and the Internet.
Downstream	The direction from the head-end towards the subscriber.
DSA	Dynamic Service Addition. A DOCSIS MAC management message requesting the dynamic creation of a new Service Flow. New SFs are created with a three-message exchange of a DSA-REQ, DSA-RSP, and DSA-ACK.
DSC	Dynamic Service Change. A DOCSIS MAC management message requesting a change to the attributes of a Service Flow. SFs are changed with a three-message exchange of a DSC-REQ, DSC-RSP, and DSC-ACK.
DSD	Dynamic Service Delete. A DOCSIS MAC management message requesting the deletion of a Service Flow. SFs are deleted with a two-message exchange of a DSD-REQ and DSD-ACK.

Head-end	The origination point in most cable systems of the subscriber video signals. It is generally also the location of the CMTS.
PHS	Payload Header Suppression. A feature of DOCSIS 1.1 and 2.0 in which header bytes that are common in a sequence of packets of a Service Flow are replaced by a one-byte PHSI Index (PHSI) when transmitting the packet on the RF network.
primary SF	Primary Service Flow. All CMs have a Primary Upstream Service Flow and a Primary Downstream Service Flow. They provide a default path for forwarded packets that are not classified to any other Service Flow.
Provisioned QPS	A QoS Parameter Set describing an envelope of service within which a Service Flow is authorized to request admission. All existing Service Flows must have a non-empty Provisioned QPS; thus, all SFs are considered to be "Provisioned".
RF	Radio Frequency. In particular, this abbreviation refers to the radio frequencies for Cable Television (CATV).
SCN	Service Class Name. A named set of QoS parameters. A Service Flow may or may not be associated with a single named Service Class. A Service Class has as an attribute a QoS Parameter Set that is used as the default set of values for all Service Flows belonging to the Service Class.
SID	Service ID. A 16-bit unsigned integer assigned by the CMTS for an Upstream Service Flow with a non-empty Active QoS Parameter Set.
SF	Service Flow. A unidirectional stream of packets between the CM and CMTS. SFs are characterized as upstream or downstream. The SF is the fundamental unit of service provided on a DOCSIS CATV network.
SFID	Service Flow ID. A 32-bit unsigned integer assigned by the CMTS to each Service Flow.
Upstream	The direction from a subscriber CM to the head-end CMTS.

## 2. Overview

This MIB module provides a set of objects required for the management of DOCSIS 1.1 and 2.0 compliant Cable Modems (CM) and Cable Modem Termination Systems (CMTS). The specification is derived from the DOCSIS 2.0 Radio Frequency Interface specification [4]. Please note that the referenced DOCSIS specifications only requires Cable Modems to process IPv4 customer traffic. Design choices in this MIB module reflect those requirements. Future versions of the DOCSIS standard are expected to require support for IPv6 as well.

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [5].

### 2.1. Textual Conventions

The textual convention "DocsIetfQosRfMacIfDirection" is defined to indicate the direction of a packet classifier relative to an interface. It takes the values of either downstream(1) or upstream(2).

The textual convention "DocsIetfQosBitRate" corresponds to the bits per second as defined for QoS Parameter Sets in DOCSIS 1.1 and 2.0. This definition includes all bits of the Ethernet MAC frame as transmitted on the RF network, starting with the Destination Address and ending with the Ethernet Frame Check Sequence (FCS). It does NOT include bits in the DOCSIS MAC header.

### 2.2. MIB Organization

The structure of the IPCDN QoS MIB module (DOCS-IETF-QOS-MIB) is summarized below:

```
docsIetfQosMIB
  docsIetfQosMIBObjects
    docsIetfQosPktClassTable
      docsIetfQosPktClassEntry
        docsIetfQosPktClassId

This MIB module is organized as 11 tables. Most tables are implemented in both the CM and CMTS; the docsIetfQosUpstreamStatsTable and docsIetfQosServiceFlowLogTable are implemented on the CMTS only.

#### 2.2.1. docsIetfQosPktClassTable

The docsIetfQosPktClassTable reports the Service Flow Classifiers implemented by the managed device. The table is indexed by the tuple { ifIndex, docsIetfQosServiceFlowId, docsIetfQosPktClassId }. The ifIndex corresponds to a CATV MAC interface. Each CATV MAC interface has a set of Service Flows identified with a docsIetfQosServiceFlowId value that is unique for that interface. Each Service Flow may have a number of packet classifiers that map packets to the flow. The ClassifierId for the classifier is unique only within a particular Service Flow.

The semantics of packet classification are provided in [4]. Briefly, the DOCSIS MAC interface calls for matching packets based on values within the 802.2 (LLC), 802.3, IP, and/or UDP/TCP headers. Packets that map more than one classifier are prioritized according to their docsIetfQosPktClassPriority values. The docsIetfQosServiceFlowId (an index object) indicates to which Service Flow the packet is classified.

The docsIetfQosPktClassTable is distinct from the docsDevIpFilterTable of [6] in that docsIetfQosPktClassTable is intended only to reflect the state of the Service Flow Classifiers. Service Flow Classifiers may be created only via a CM configuration file or from the Dynamic Service Addition (DSA) messages. For this reason, docsIetfQosPktClassTable is read-only.

The docsDevIpFilterTable is intended for external policy-based administration of packet classifiers. See the section "Externally Administered Classification", below.

### 2.2.2. docsIetfQosParamSetTable

The `docsIetfQosParamSetTable` reports the values of QoS Parameter Set as defined in Section C.2.2 of [4].

In general, a Service Flow is associated with three different QoS Parameter Sets (QPSs): an "active" QPS, an "admitted" QPS, and a "provisioned" or "authorized" QPS. The relationship of these three sets is represented below:

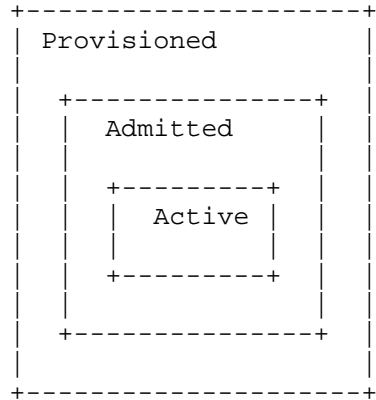

Figure 1: QoS Parameter Sets

The Provisioned QPS describes the maximum service envelope for which the SF is authorized. The Admitted QPS is the set of services for which a Service Flow has requested admission to the DOCSIS RF network, but which is not yet active. The Admitted QPS is used during the two-phase process of IP Telephony/PacketCable Service Flow admission to admit the bandwidth for a bidirectional voice call when the far end is ringing. Because ringing may occur for up to four minutes, this permits the bandwidth to be reserved but not actually consumed during this interval. The Active QPS is the set of services actually being used by the Service Flow. The DOCSIS v1.1 specification [4] defines what it means for a QPS envelope to be "within" another. In general, an inner QPS is considered "within" an outer QPS when all QoS parameters represent demands of equal or fewer resources of the network.

In addition to its use as an attribute of a Service Flow, a QPS is also an attribute of a Service Class. A DOCSIS CM configuration file or DSA message may request the creation of a new SF and give only the Service Class Name. The CMTS "expands the macro" of a Service Class Name creation by populating the Provisioned, Admitted, and/or Active QPSs of the Service Flow with the QPS of the Service Class Name. All

the QPSs of a Service Flow must be expansions of the same Service Class, and in this case the SF is said to "belong" to the Service Class. Changing the contents of a Service Class' QPS does not affect the QPS of any Service Flow earlier expanded from that Service Class name. Only the CMTS implements docsIetfQosServiceClassTable.

See [4], section 8, for a full description and the theory of operation of DOCSIS 1.1 QoS operation.

The docsIetfQosParamSetTable sets are indexed by { ifIndex, docsIetfQosServiceFlowId, docsIetfQosParamSetType}. ifIndex indicates a particular "DOCSIS MAC Domain". docsIetfQosServiceFlowId uniquely identifies a Service Flow on that MAC domain. The docsIetfQosParamSetType indicates whether the row describes an active, admitted, or provisioned QoS Parameter Set.

The docsIetfQosParamSetTable is read-only because it indicates the QoS Parameter Set contents as defined by DOCSIS signaling. The docsIetfQosServiceClassTable is read-create to permit managers to define a template of QoS Parameters that can be referenced by DOCSIS modems when creating their QoS Parameter Sets.

#### 2.2.2.1. Interoperation with DOCSIS 1.0

The DOCS-IF-MIB [7] specifies a docsIfQosProfileTable to describe the set of Class Of Service (COS) parameters associated with a COS "profile". The docsIfCmServiceTable, which contains one entry per SID, references this table with a docsIfCmServiceQosProfile number.

The DOCSIS 1.1 and 2.0 CM registration process allows a modem to register as operating with DOCSIS 1.0, DOCSIS 1.1, or DOCSIS 2.0 functionality. For ease of expression, we call a modem registering with DOCSIS 1.0 functionality a "DOCSIS 1.0 modem", regardless of the modem's capabilities.

A CMTS or CM supporting DOCSIS 1.0, as well as DOCSIS 1.1, and/or DOCSIS 2.0 implements both the tables of [7] and the tables of this MIB module. The interoperation goal is that before modem registration, the DOCSIS 1.0 MIB [7] applies. After registration, either the DOCSIS 1.0 or DOCSIS 1.1/2.0 MIB applies, depending on the mode with which the modem registered. The specific interoperation rules are:

1. When a CM initially ranges, the CM implements a row in the DOCS-IF-MIB docsIfCmServiceTable, and the CMTS implements a row in the DOCS-IF-MIB docsIfCmtsServiceTable corresponding to the default upstream Service ID (SID) used for pre-registration

upstream traffic. For historical compatibility, a row may be created for the docsIfQosProfileTable with default values, which may be referenced by the docsIfCmServiceTable entries.

2. Both a CMTS and CM implementing this MIB MUST NOT implement docsIetfQosParamSetTable or docsIetfQosServiceFlowTable rows until after the CM registers with DOCSIS 1.1 or 2.0 modem operation.
3. When a modem registers with the CMTS as a "DOCSIS 1.1" or "DOCSIS 2.0" modem, any exclusively-referenced row in DOCS-IF-MIB docsIfQosProfileTable representing the modem's upstream QoS profile for pre-registration traffic MUST be removed. Multiply-referenced rows may remain. The docsIfCmServiceQosProfile object in the CM's row of docsIfCmServiceTable MUST be set to zero. The docsIfCmServiceTable row for the DOCSIS 1.1 or DOCSIS 2.0 modem continues to exist, and the various statistic objects in that row are incremented. The CMTS should retain a docsIfCmtsServiceTable entry for the DOCSIS 1.1 or DOCSIS 2.0 CM.
4. When a DOCSIS 1.1 or DOCSIS 2.0 modem registers, both the CMTS and CM represent all Service Flows described in the modem configuration file in docsIetfQosParamSetTable and docsIetfQosServiceFlowTable.
5. DOCSIS 1.0 modems do not have entries in the DOCS-IETF-QOS-MIB.

#### 2.2.3. docsIetfQosServiceFlowTable

The docsIetfQosServiceFlowTable provides read-only information about all the Service Flows known by the device. It is indexed by the combination of { ifIndex, docsQosServiceFlowId }, where ifIndex corresponds to a CATV MAC interface and docsIetfQosServiceFlowId is the 32-bit integer assigned by the CMTS controlling the MAC domain. A CM typically has only a single CATV MAC interface, whereas a CMTS may have several. See [7] for a description of the ifIndex numbering for DOCSIS devices.

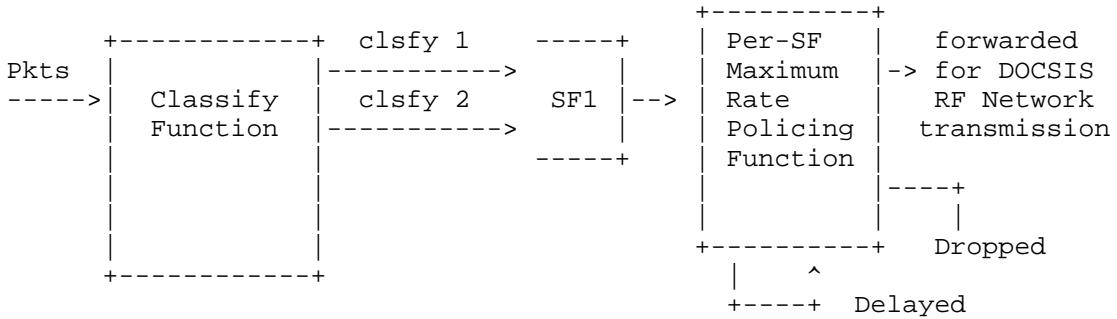

The table indicates whether a given SF is in the upstream or downstream direction, and whether it is the "primary" SF in that direction. The primary SF carries traffic that is not otherwise classified to any other SF in that direction.

#### 2.2.4. docsIetfQosServiceFlowStatsTable

The `docsIetfQosServiceFlowStatsTable` provides statistics for all currently existing SFs known by the managed device. It provides basic packet and octet counters, as well as certain other SF-specific stats such as the time at which the flow was created and how many seconds it has been active.

The table also provides objects that can be used to fine-tune admission control decisions; namely, the number of packets dropped or delayed due to QoS policing decisions enforced by the managed device.

The model of the Service Flows stats table is that there exists a Service Flow Classification function followed by a Service Flow maximum rate Policing function for packets transmitted onto the DOCSIS RF network, as depicted below.

Packets intended for transmission onto the DOCSIS RF network (upstream or downstream) are first classified to a Service Flow by matching one of several possible classifiers associated with that Service Flow. The `docsIetfQosPktClassPkts` count includes the number of packets that match the classifier, regardless of the eventual disposition of the packet.

DOCSIS requires that each Service Flow be policed to maintain a maximum rate of transmission. This is performed by either dropping or delaying a packet on that Service Flow. The `docsIetfQosServiceFlowPolicedDropPkts` object counts the number of Service Flow packets dropped by the policing function. The `docsIetfQosServiceFlowPolicedDelayPkts` counts the number of packets delayed but still forwarded. The `docsIetfQosServiceFlowPkts` object counts the total number of packets forwarded beyond the policing function intended for eventual transmission onto the DOCSIS RF network. Although packets may later be dropped by other functions (e.g., a transmit queue overflow on a DOCSIS hardware transmitter), the `docsIetfQos` MIB per service-flow counters are not affected.

#### 2.2.5. docsIetfQosUpstreamStatsTable

This table provides statistics that are measured only at the CMTS in the upstream direction. These include counts of fragmentation headers received, fragments discarded, and concatenation headers received.

#### 2.2.6. docsIetfQosDynamicServiceStatsTable

This table provides read-only stats on the operation of the Dynamic Service state machines as specified in section 9.4 of [4]. It provides a set of 14 counters in each direction for a DOCSIS MAC layer interface. That is, each DOCSIS MAC layer interface has one row for downstream stats and a second row for upstream stats.

Eight of the counters are DSx packet type counts, one counter for each of the eight DSx packet types. For example, the docsIetfQosDSAReqs object in the upstream row at the CMTS counts the number of DSA-REQ messages received by the CMTS from that interface. The docsIetfQosDSAReqs object in the downstream row at the CMTS counts the number of DSA-REQ messages transmitted by the CMTS on that interface.

The remaining six counters per (interface, direction) combination count the number of successful and unsuccessful transactions that were initiated on the interface and direction. For example, the upstream docsIetfQosDynamicAdds on a CMTS is the number of successfully completed CM-initiated dynamic additions, because at the CMTS a CM-initiated DSA starts in the upstream direction. The downstream docsIetfQosDynamicAdds at a CMTS is the number of successful CMTS-initiated DSA transactions.

Dynamic service transactions can fail for a number of reasons, as listed in the state machines of section 9.4. Rather than include still more counters for each different failure reason, they are grouped into a single count, e.g., docsIetfQosDynamicAddFails. Again, this object exists in both directions, so that locally originated and remotely originated transaction failures are counted separately. Further troubleshooting of transaction failures will require vendor-specific queries and operation.

#### 2.2.7. docsIetfQosServiceFlowLogTable

This table contains a log of the Service Flows that no longer exist in the docsIetfQosServiceFlowTable. It is intended to be periodically polled by traffic monitoring and billing agents. It is implemented only at the CMTS.

It contains a chronological log of SF session statistics, including a total count of packets and octets transferred on the SF. It includes time stamps of the SF creation and deletion time, and of its number of active seconds. The active second count is the count of seconds that the SF had a non-empty Active QoS Parameter Set, i.e., it was eligible to pass data. For unicast SFs, it includes the CM MAC address associated with the flow for billing reference purposes.

The maximum number of log records kept by a CMTS and the duration that a log record is maintained in the table are vendor-specific. An explicit control object is provided so that the monitoring application can explicitly delete records it has read.

#### 2.2.8. docsIetfQosServiceClassTable

This table defines the Service Class Name and references a QoS Parameter Set for each Service Class defined in a CMTS. It is indexed by the Service Class Name string itself. The table is read-create on a CMTS, and is not implemented in a CM. Each entry of the docsIetfQosServiceClassTable should define a template for flows in a given direction (upstream or downstream). Some parameters of the docsIetfQosServiceClassTable are specific to a particular direction, and so their values are not applicable when used as a template for flows in the other direction.

#### 2.2.9. docsIetfQosServiceClassPolicyTable

The docsIetfQosServiceClassPolicyTable can be referenced by the docsDevFilterPolicyTable of [6] in order to have a "policy" that classifies packets to a named Service Class. This is one mechanism by which "external" entities (such as an SNMP manager) may control the classification of a packet for QoS purposes. Entries are indexed by a small-integer docsIetfQosServiceClassPolicyIndex. They provide a Service Class Name and a Rule Priority. A policy referencing a row of this table intends the packet to be forwarded on a Service Flow "belonging" to the named Service Class. See section 3, "Externally Administered Classification", below.

This table is implemented on both the CM and CMTS, and is read-create on both.

### 2.2.10. docsIetfQosPHSTable

The Payload Header Suppression (PHS) feature of DOCSIS 1.1 and 2.0 permits packets to replace the unchanging bytes of the Ethernet, IP, and UDP headers with a one-byte index when transmitting on the cable network. This is especially useful for IP Telephony packets, where such suppression can result in almost twice the number of calls supported within the same upstream channel.

Each entry of the table corresponds to a PHS Rule as described in section 8.4 of [4]. The rules are identified by their corresponding Service Flow ID and docsIetfQosPktClassId. A PHS rule is associated with exactly one classifier. The table is therefore indexed by the tuple { ifIndex, docsIetfQosServiceFlowId, docsIetfQosPktClassId}.

This table is read-only, and MUST be implemented on both the CM and CMTS when PHS is supported.

### 2.2.11 docsIetfQosCmtsMacToSrvFlowTable

The docsIetfQosCmtsMacToSrvFlowTable describes the mapping of CM MAC addresses to the Service Flow IDs that are uniquely identified with that CM. External applications may collect statistics on all packets flowing through a CM by determining the SFID of all of its flows, and then collecting the statistics of packets and bytes for each flow.

Downstream multicast Service Flows are not indicated in the docsIetfQosCmtsMacToSrvFlowTable because they are not associated with only one CM.

## 3. Externally Administered Classification

DOCSIS 1.1 and 2.0 provide rich semantics for the classification of packets to Service Flows with the Service Flow Classifier table. Service Flow Classifiers may be created statically in the DOCSIS CM configuration file, or may be created dynamically with Dynamic Service Addition (DSA) and Dynamic Service Change (DSC) DOCSIS MAC messages.

Several major issues arose with the concept of externally administered classification; e.g., should an external SNMP manager be permitted to create classification rows? One problem was the coordination of classifier IDs because such an approach would require either separate classifier ID number spaces or objects to coordinate both internal and external classifier ID assignments. A more serious problem, however, was that external creation of SF Classifiers would require "knowledge" of the individual Service Flow ID for Service Flows by external applications. It was strongly felt by the

committee that SFIDs should remain internal DOCSIS objects, and not be transmitted as part of protocol flows, e.g., for IP packet telephony signaling. DOCSIS 1.1 introduced the concept of named Service Classes for ease of administration within a domain of CMs and CMTSs. What was desired was to permit external classification of packets to a Service Class, not to a particular Service Flow.

The DOCSIS committee therefore decided to use the already-defined IP Packet Filter Table [6] for the external classification of packets for QoS purposes. The docsDevIpPacketFilterTable defines similar packet matching criteria as does docsIetfQosPktClassTable, but it matches a packet to an arbitrary "policy set" instead of a particular Service Flow. One of the policies in the policy set then selects the Service Class of the SF on which to forward the packet. The docsIetfQosServiceClassPolicyTable of this MIB module defines the Service Class Name to which a packet is classified.

The interaction of external and internal packet classification is depicted below.

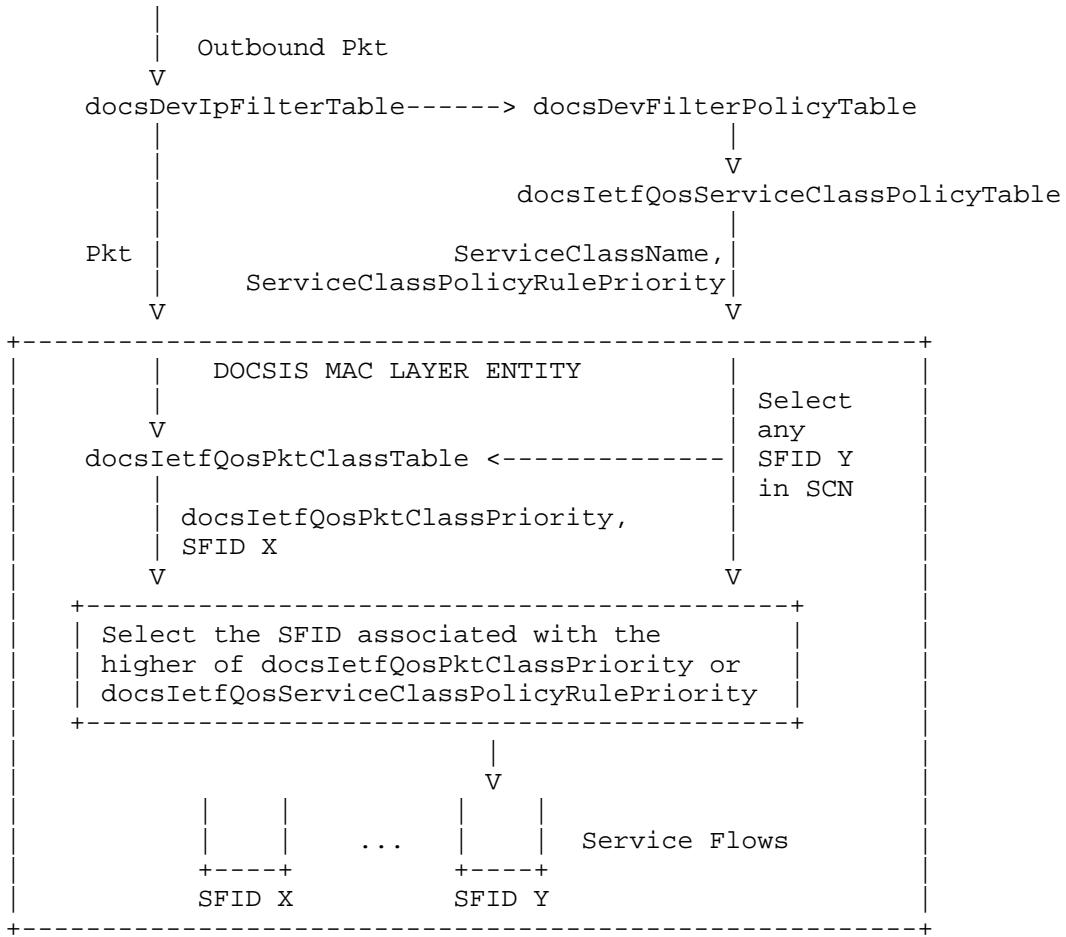

Figure 2: DOCSIS Packet Classification

The processing of an outgoing packet proceeds as follows:

1. The packet is first checked for matches with rows of the `docsDevIpFilterTable`. If it matches, the matching row provides a `docsDevFilterPolicyId` integer.
2. The `docsDevFilterPolicyId` indexes into one (or more) rows of `docsDevFilterPolicyTable`. Each row provides an arbitrary `RowPointer` (`docsDevFilterPolicyPtr`), corresponding to a policy to be applied to the packet.

3. This MIB module defines a `docsIetfQosServiceClassPolicyTable` whose entries may be pointed to by `docsDevFilterPolicyPtr` in order to classify packets administratively to a named DOCSIS Service Class. The `docsIetfQosServiceClassPolicyEntry` provides a Service Class Name (SCN) as `docsIetfQosServiceClassPolicyName` and a classification rule priority as `docsIetfQosServiceClassPolicyRulePriority`. These are submitted to the device's DOCSIS MAC Layer entity as a special form of the `MAC_DATA.request` primitive, as described in Section E.2.1 of [4].
4. The MAC Layer selects an SFID ("Y") of an active Service Flow belonging to the named class, choosing an SF arbitrarily if there is more than one.
5. The packet is then classified according to the `docsIetfQosPktClassTable`, which may classify the packet to a different SFID "X". Associated with the classifier is a `docsIetfQosPktClassPriority`.
6. In the event of a conflict between the SCN-determined SFID and the classified SFID, the greater of `docsIetfQosPktClassPriority` and `docsIetfQosServiceClassPolicyRulePriority` determines which SFID is selected to forward the packet.

A packet that does not match a `docsIetfQosServiceClassPolicyEntry` is directly submitted to the DOCSIS MAC layer, where the `docsIetfQosPktClassTable` selects the SID on which it is to be forwarded.

By convention (in [4]), the "internal" `docsIetfQosPktClassPriority` values should be in the range 64-191, while the "external" priorities may be either in the range 192-255 to override the internal classification or in the range 0-63 to be overridden by internal classification.

This classification mechanism applies both upstream from the CM and downstream from the CMTS.

#### 4. DOCSIS and IPv4 Type-of-Service (ToS) Field

The DOCSIS-IETF-QOS-MIB MIB module relies on the DOCSIS MAC layer protocols and uses objects that reflect the IPv4 Type-of-Service (ToS) octet as defined in [14]. The applicability of these objects is limited to the DOCSIS access network. The past and current versions of the DOCSIS specifications for which this MIB module is defined do not reflect Differentiated Services [9] on the DOCSIS access network. However, with proper selection of values for these

objects, the network operator can enforce Differentiated Services Per-hop Behaviors (PHBs) on the DOCSIS Access Network, and can configure the modification of the DSCP for certain packet flows as they enter the metro network from the access network. Essentially this makes the DOCSIS access network TOS marking compatible with the wider use of DSCP outside DOCSIS networks. Note that because the entire IPv4 TOS octet may be available for modification via the latter mechanism (due to the current MAC level DOCSIS protocols and CLI interface configuration), it is possible that the DOCSIS network could be configured to modify the Explicit Congestion Notification (ECN) bits [10] of certain packets. This modification of the ECN bits is prevented by the MIB module's design. The MIB module prohibits the modification of the TOS octet (read-only objects: docsIetfQosPktClassIpTosLow, docsIetfQosPktClassIpTosHigh, docsIetfQosPktClassIpTosMask, docsIetfQosParamSetTosAndMask, docsIetfQosParamSetTosOrMask) and allows the DSCP field to be modified (read-create object: docsIetfQosServiceClassDSCPOverwrite).

## 5. Definitions

This MIB module refers to the SNMPv2-SMI [1] MIB module, SNMPv2-TC [2] MIB module, SNMPv2-CONF [3] MIB Module, DOCSIS RFI Specification SP-RFIV2.0-I06-040804 [4], INET-ADDRESS-MIB [8] MIB module, IF-MIB [11] MIB module, SNMP-FRAMEWORK-MIB [12] MIB module, and DIFFSERV-DSCP-TC [13] MIB module.

-- Packet Classifier Table  

--  

docsIetfQosPktClassTable OBJECT-TYPE
    SYNTAX          SEQUENCE OF DocsIetfQosPktClassEntry
    MAX-ACCESS     not-accessible
    STATUS         current
    DESCRIPTION    "This table describes the packet classification
                    configured on the CM or CMTS.
                    The model is that a packet either received
                    as input from an interface or transmitted
                    for output on an interface may be compared
                    against an ordered list of rules pertaining to
                    the packet contents. Each rule is a row of this
                    table. A matching rule provides a Service Flow
                    ID to which the packet is classified.
                    All rules need to match for a packet to match
                    a classifier.

                    The objects in this row correspond to a set of
                    Classifier Encoding parameters in a DOCSIS
                    MAC management message. The
                    docsIetfQosPktClassBitMap indicates which
                    particular parameters were present in the
                    classifier as signaled in the DOCSIS message.
                    If the referenced parameter was not present
                    in the signaled DOCSIS 1.1 and 2.0 Classifier, the
                    corresponding object in this row reports a
                    value as specified in the DESCRIPTION section."

**MAX-ACCESS** read-only  
**STATUS** current  
**DESCRIPTION** "This object indicates the format of the layer 3 protocol ID in the Ethernet packet. A value of none(0) means that the rule does not use the layer 3 protocol type as a matching criteria.  
 A value of ethertype(1) means that the rule applies only to frames that contain an EtherType value. EtherType values are contained in packets using the Dec-Intel-Xerox (DIX) encapsulation or the RFC1042 Sub-Network Access Protocol (SNAP) encapsulation formats.  
 A value of dsap(2) means that the rule applies

only to frames using the IEEE802.3 encapsulation format with a Destination Service Access Point (DSAP) other than 0xAA (which is reserved for SNAP).

A value of mac(3) means that the rule applies only to MAC management messages for MAC management messages.

A value of all(4) means that the rule matches all Ethernet packets.

If the Ethernet frame contains an 802.1P/Q Tag header (i.e., EtherType 0x8100), this object applies to the embedded EtherType field within the 802.1P/Q header.

If the referenced parameter is not present in a classifier, this object reports the value of 0."

STATUS      current
DESCRIPTION
"This object indicates which parameter encodings
were actually present in the DOCSIS packet
classifier encoding signaled in the DOCSIS message
that created or modified the classifier. Note that
Dynamic Service Change messages have replace
semantics, so that all non-default parameters must
be present whether the classifier is being created
or changed.

A bit of this object is set to 1 if the parameter
indicated by the comment was present in the
classifier encoding, and to 0 otherwise.

Note that BITS are encoded most significant bit
first, so that if, for example, bits 6 and 7 are
set, this object is encoded as the octet string
'030000'H.

-- QOS Parameter Set Table
--

```

```
docsIetfQosParamSetTable OBJECT-TYPE
  SYNTAX          SEQUENCE OF DocsIetfQosParamSetEntry
  MAX-ACCESS     not-accessible
  STATUS         current
  DESCRIPTION    "This table describes the set of DOCSIS 1.1 and 2.0
                  QOS parameters defined in a managed device."
```

The ifIndex index specifies a DOCSIS MAC Domain.  
 The docsIetfQosServiceFlowId index specifies a particular Service Flow.  
 The docsIetfQosParamSetType index indicates whether the active, admitted, or provisioned QOS Parameter Set is being described by the row.

Only the QOS Parameter Sets of DOCSIS 1.1 and 2.0 Service Flows are represented in this table.

DOCSIS 1.0 QOS service profiles are not represented in this table.

Each row corresponds to a DOCSIS QOS Parameter Set as signaled via DOCSIS MAC management messages.  
 Each object in the row corresponds to one or part of one DOCSIS 1.1 Service Flow Encoding.  
 The docsIetfQosParamSetBitMap object in the row indicates which particular parameters were signaled in the original registration or dynamic service request message that created the QOS Parameter Set.

In many cases, even if a QOS Parameter Set parameter was not signaled, the DOCSIS specification calls for a default value to be used. That default value is reported as the value of the corresponding object in this row.

Many objects are not applicable, depending on the Service Flow direction or upstream scheduling type. The object value reported in this case is specified in the DESCRIPTION clause."

#### docsIetfQosParamSetTosAndMask OBJECT-TYPE

SYNTAX	OCTET STRING (SIZE(1))
MAX-ACCESS	read-only
STATUS	current
DESCRIPTION	"Specifies the AND mask for the IP TOS byte for overwriting IP packet's TOS value. The IP packet TOS byte is bitwise ANDed with docsIetfQosParamSetTosAndMask, and the result is bitwise ORed with docsIetfQosParamSetTosOrMask and the result is written to the IP packet TOS byte. A value of 'FF'H for docsIetfQosParamSetTosAndMask and a value of '00'H for docsIetfQosParamSetTosOrMask means that the IP Packet TOS byte is not overwritten.

This combination is reported if the referenced parameter is not present in a QoS Parameter Set.

The IP TOS octet as originally defined in RFC 791 has been superseded by the 6-bit Differentiated Services Field (DSField, RFC 3260) and the 2-bit Explicit Congestion Notification Field (ECN field, RFC 3168). Network operators SHOULD avoid specifying values of `docsIetfQosParamSetTosAndMask` and `docsIetfQosParamSetTosORMask` that would result in the modification of the ECN bits.

In particular, operators should not use values of `docsIetfQosParamSetTosAndMask` that have either of the least-significant two bits set to 0. Similarly, operators should not use values of `docsIetfQosParamSetTosORMask` that have either of the least-significant two bits set to 1.

Even though this object is only enforced by the Cable Modem Termination System (CMTS), Cable Modems MUST report the value as signaled in the referenced parameter."

-- A 32-bit mask represented most significant byte

```

-- first. The 32-bit integer represented in this  
 -- manner equals the binary value of the referenced  
 -- integer parameter of the DOCSIS RFI  
 -- specification.  
 -- The BITS syntax is not used in order to avoid  
 -- the confusion caused by different bit-numbering  
 -- conventions.

**MAX-ACCESS** read-only  
**STATUS** current  
**DESCRIPTION** "Specifies which transmit interval opportunities  
 the CM omits for upstream transmission requests and  
 packet transmissions. This object takes its  
 default value for downstream Service Flows.

Unless otherwise indicated, a bit value of 1 means  
 that a CM must not use that opportunity for  
 upstream transmission.

If bit 0 is the least significant bit of the  
 least significant (4th) octet, and if bit number  
 is increased with significance, the bit definitions  
 are defined as follows:

```
broadcastReqOpp(0):
    all CMs broadcast request opportunities

priorityReqMulticastReq(1):
    priority request multicast request
    opportunities

reqDataForReq(2):
    request/data opportunities for requests

reqDataForData(3):
    request/data opportunities for data

piggybackReqWithData(4):
    piggyback requests with data

concatenateData(5):
    concatenate data

fragmentData(6):
    fragment data

suppresspayloadheaders(7):
    suppress payload headers
```

```
dropPktsExceedUGSize(8):
    A value of 1 means that the Service Flow must
    drop packets that do not fit in the Unsolicited
    Grant size.
```

If the referenced parameter is not present in  
a QOS Parameter Set, the value of this object is  
reported as '00000000'H."

MAX-ACCESS

STATUS

DESCRIPTION

"This object indicates the set of QOS Parameter  
Set parameters actually signaled in the  
DOCSIS registration or dynamic service request  
message that created or modified the QOS Parameter  
Set. A bit is set to 1 when the parameter described  
by the indicated reference section is present  
in the original request.

Note that when Service Class names are expanded,  
the registration or dynamic response message may  
contain parameters as expanded by the CMTS based

on a stored service class. These expanded parameters are not indicated by a 1 bit in this object.

Note that even though some QoS Parameter Set parameters may not be signaled in a message (so that the parameter's bit in this object is 0), the DOCSIS specification requires that default values be used. These default values are reported as the corresponding object's value in the row.

Note that BITS objects are encoded most significant bit first. For example, if bits 1 and 16 are set, the value of this object is the octet string '400080'H."

MAX-ACCESS     read-only
STATUS          current
DESCRIPTION    "For outgoing Service Flows, this object counts the
               number of Packet Data PDUs forwarded to this
               Service Flow. For incoming upstream CMTS service
               flows, this object counts the number of Packet
               Data PDUs actually received on the Service Flow
               identified by the SID for which the packet was
               scheduled. CMs not classifying downstream packets
               may report this object's value as 0 for downstream
               Service Flows. This object does not count
               MAC-specific management messages.

               Particularly for UGS flows, packets sent on the
               primary Service Flow in violation of the UGS grant
               size should be counted only by the instance of this
               object that is associated with the primary service

```

flow.

Unclassified upstream user data packets (i.e., non-MAC-management) forwarded to the primary upstream Service Flow should be counted by the instance of this object that is associated with the primary service flow.

This object does include packets counted by `docsIetfQosServiceFlowPolicedDelayPkts`, but does not include packets counted by `docsIetfQosServiceFlowPolicedDropPkts` and `docsIetfQosServiceFlowPHSUnknowns`.

This counter's last discontinuity is the `ifCounterDiscontinuityTime` for the same `ifIndex` that indexes this object."

docsIetfQosServiceClassEntry OBJECT-TYPE
    SYNTAX      DocsIetfQosServiceClassEntry
    MAX-ACCESS  not-accessible
    STATUS      current
    DESCRIPTION "A provisioned service class on a CMTS.
                 Each entry defines a template for certain
                 DOCSIS QOS Parameter Set values. When a CM
                 creates or modifies an Admitted QOS Parameter Set
                 for a Service Flow, it may reference a Service Class
                 Name instead of providing explicit QOS Parameter
                 Set values. In this case, the CMTS populates
                 the QOS Parameter Set with the applicable
                 corresponding values from the named Service Class.
                 Subsequent changes to a Service Class row do not
                 affect the QOS Parameter Set values of any service
                 flows already admitted.

                 A service class template applies to only
                 a single direction, as indicated in the
                 docsIetfQosServiceClassDirection object."

MAX-ACCESS       read-only
STATUS          current
DESCRIPTION      "Payload header suppression mask defines the
                  bit mask that is used in combination with the
                  docsIetfQosPHSField. It defines which bytes in
                  the header must be suppressed/restored by the
                  sending or receiving device.

Each bit of this bit mask corresponds to a byte
in the docsIetfQosPHSField, with the least

```

significant bit corresponding to the first byte of the docsIetfQosPHSField.

Each bit of the bit mask specifies whether the corresponding byte should be suppressed in the packet. A bit value of '1' indicates that the byte should be suppressed by the sending device and restored by the receiving device. A bit value of '0' indicates that the byte should not be suppressed by the sending device or restored by the receiving device.

If the bit mask does not contain a bit for each byte in the docsIetfQosPHSField, then the bit mask is extended with bit values of '1' to be the necessary length."

## 6. Security Considerations

This MIB module relates to an agent that will provide metropolitan public Internet access. As such, improper manipulation of the objects represented by this MIB module may result in denial of service to a large number of end-users [6]. Manipulation of the docsIetfQosServiceClassTable and docsIetfQosServiceClassPolicyTable may allow an end-user to increase his or her service levels, or affect other end-users in either a positive or negative manner. In addition, manipulation of docsIetfQosServiceFlowLogControl could allow an attacker to remove logs of packet and byte counts forwarded on a Service Flow. If such logs were used for billing, the attacker would obtain free service.

There are a number of management objects defined in this MIB module with a MAX-ACCESS clause of read-write and/or read-create. Such objects may be considered sensitive or vulnerable in some network environments. The support for SET operations in a non-secure environment without proper protection can have a negative effect on network operations. These are the tables and objects and their sensitivity/vulnerability:

- o The docsIetfQosServiceClassTable provides a template of QOS parameters such as maximum rate limits for a named service class. Changing these parameters would allow an attacker to obtain an unauthorized class of service.
- o The docsIetfQosServiceClassPolicyTable applies CMTS vendor proprietary policies for packet forwarding, including dropping, scheduling, notification, or other policies. Changing this table could allow an attacker to deny service to all subscribers of the CMTS or could grant the attacker unauthorized forwarding policies.
- o The docsIetfQosServiceFlowLogControl object controls the deletion of entries in the docsIetfQosServiceFlowLogTable, which acts as a historical "detail record" of DOCSIS Service Flow packets and bytes transmitted. Such records may be used for billing purposes, so the unauthorized deletion of the records can result in free service.

Some of the readable objects in this MIB module (i.e., objects with a MAX-ACCESS other than not-accessible) may be considered sensitive or vulnerable in some network environments. It is thus important to

control even GET access to these objects and possibly to even encrypt the values of these objects when sending them over the network via SNMP. These are the tables and objects and their sensitivity/vulnerability:

- o Unauthorized SNMP GET access of the docsIetfQosPktClassTable or docsIetfQosPHSTable can allow an attacker to learn IP addresses permitted to have enhanced quality of service, for possible spoofing. This table typically contains the IP addresses involved in voice-over-IP sessions, for example.
- o Unauthorized SNMP GET access of the docsIetfQosParamSetTable allows an attacker to learn the names of Service Classes that are permitted to have enhanced QoS service, and the values of that enhanced service. That name can be referenced in an unauthorized DOCSIS cable modem configuration file to obtain enhanced service.
- o Unauthorized SNMP GET access of the docsIetfQosServiceFlowTable can tell an attacker when Service Flows are active, e.g., when a voice-over-IP call is in progress.

Unauthorized SNMP GET access of the docsIetfQosServiceFlowLogTable can expose private information about network usage.

- o Unauthorized SNMP GET access of the docsIetfQosServiceFlowStatsTable, docsIetfQosUpstreamStatsTable, docsIetfQosDynamicServiceStatsTable, docsIetfQosServiceFlowLogTable, and docsIetfQosCmtsMacToSrvFlowTable can tell an attacker the volume of traffic to and from any Service Flow in the system, resulting in loss of privacy of the amount and direction of data transfer.

SNMP versions prior to SNMPv3 did not include adequate security. Even if the network itself is secure (for example by using IPSec), even then, there is no control as to who on the secure network is allowed to access and GET/SET (read/change/create/delete) the objects in this MIB module. It is RECOMMENDED that implementers consider the security features as provided by the SNMPv3 framework (see [15], section 8), including full support for the SNMPv3 cryptographic mechanisms (for authentication and privacy). Further, deployment of SNMP versions prior to SNMPv3 is NOT RECOMMENDED. Instead, it is RECOMMENDED to deploy SNMPv3 and to enable cryptographic security. It is then a customer/operator responsibility to ensure that the SNMP

entity giving access to an instance of this MIB module, is properly configured to give access to the objects only to those principals (users) that have legitimate rights to indeed GET or SET (change/create/delete) them.

## 7. IANA Considerations

The MIB module in this document uses the following IANA-assigned OBJECT IDENTIFIER values recorded in the SMI Numbers registry:

Descriptor	OBJECT IDENTIFIER Value
docsIetfQosMIB	{ mib-2 127 }

## 8. Acknowledgements

The authors gratefully acknowledge the comments and suggestions of the IP over Cable Data Network (IPCDN) Working Group (especially the co-chairs Richard Woundy and Jean-Francois Mule) as well as the contributions of the Operation and Management Area Director, Bert Wijnen.
